

Functional Reactive Programming and Elm

Sergei Winitzki

BayHac 2015

June 14, 2015

Part 1. Functional reactive programming and Elm

FRP has little to do with...

- multithreading, message-passing concurrency, “actors”
- distributed computing on massively parallel, load-balanced clusters
- map/reduce, “reactive extensions”, the “reactive manifesto”

FRP means (in my definition)...

- **pure functions** using **temporal types** as primitives
 - ▶ (temporal type \approx lazy stream of values)

FRP is probably most useful for:

- GUI and event-driven programming

Elm is...

- a viable implementation of FRP geared for Web GUI apps

Difficulties in reactive programming

Imperative implementation is one problem among many...

- Input signals may come at unpredictable times
 - ▶ Imperative updates are difficult to keep in the correct order
 - ▶ Flow of events becomes difficult to understand
- Asynchronous (out-of-order) callback logic becomes opaque
 - ▶ “callback hell”: deeply nested callbacks, all mutating data
- Inverted control (“the system will call you”) obscures the flow of data
- Some concurrency is usually required (e.g. background tasks)
 - ▶ Explicit multithreaded code is hard to write and debug

FRP basics

- Reactive programs work on **infinite streams** of input/output values
- Main idea: make streams **implicit**, as a new “temporal” type
 - ▶ $\Sigma\alpha$ — an infinite stream of values of type α
 - ▶ alternatively, $\Sigma\alpha$ is a value of type α that “changes with time”
- Reactive programs are viewed as **pure functions**
 - ▶ a GUI is a pure function of type $\Sigma \text{Inputs} \rightarrow \Sigma \text{View}$
 - ▶ a Web server is a pure function $\Sigma \text{Request} \rightarrow \Sigma \text{Response}$
 - ▶ all mutation is **implicit** in the program
 - ★ instead of updating an $x:\text{Int}$, we define a value of type ΣInt
 - ★ our code is 100% immutable, no side effects, no IO monads
 - ▶ asynchronous behavior is **implicit**: our code has no callbacks
 - ▶ concurrency / parallelism is **implicit**
 - ★ the FRP runtime will provide the required scheduling of events

Czaplicki's (2012) core Elm in a nutshell

- Elm is a pure polymorphic λ -calculus with products and sums
- **Temporal type** $\Sigma\alpha$ — a lazy sequence of values of type α
- Temporal **combinators** in core Elm:

`constant`: $\alpha \rightarrow \Sigma\alpha$

`map2`: $(\alpha \rightarrow \beta \rightarrow \gamma) \rightarrow \Sigma\alpha \rightarrow \Sigma\beta \rightarrow \Sigma\gamma$

`scan`: $(\alpha \rightarrow \beta \rightarrow \beta) \rightarrow \beta \rightarrow \Sigma\alpha \rightarrow \Sigma\beta$

- **No nested** temporal types: `constant (constant x)` is ill-typed!
- Domain-specific primitive types: `Bool`, `Int`, `Float`, `String`, `View`
- Standard library with data structures, HTML, HTTP, JSON, ...
 - ▶ ...and signals `Time.every`, `Mouse.position`, `Window.dimensions`, ...
 - ▶ ...and some utility functions: `map`, `merge`, `drop`, `sampleOn`, ...

Details: Elm type judgments [Czaplicki 2012]

- Polymorphically typed λ -calculus (also with temporal types)

$$\frac{\Gamma, (x : \alpha) \vdash e : \beta}{\Gamma \vdash (\lambda x. e) : \alpha \rightarrow \beta} \text{Lambda} \quad \frac{\Gamma \vdash e_1 : \alpha \rightarrow \beta \quad \Gamma \vdash e_2 : \alpha}{\Gamma \vdash (e_1 e_2) : \beta} \text{Apply}$$

- Temporal types are denoted by $\Sigma\tau$

- In these rules, type variables α, β, γ **cannot** involve Σ :

$$\frac{\Gamma \vdash e : \alpha}{\Gamma \vdash (\text{constant } e) : \Sigma\alpha} \text{Const}$$
$$\frac{\Gamma \vdash m : \alpha \rightarrow \beta \rightarrow \gamma \quad \Gamma \vdash p : \Sigma\alpha \quad \Gamma \vdash q : \Sigma\beta}{\Gamma \vdash (\text{map2 } m \ p \ q) : \Sigma\gamma} \text{Map2}$$
$$\frac{\Gamma \vdash u : \alpha \rightarrow \beta \rightarrow \beta \quad \Gamma \vdash e : \beta \quad \Gamma \vdash q : \Sigma\alpha}{\Gamma \vdash (\text{scan } u \ e \ q) : \Sigma\beta} \text{Scan}$$

Elm operational semantics 0: Current values

- An Elm program is a temporal expression of type $\dots \rightarrow \Sigma \text{View}$
 - ▶ Temporal expressions are built from **input signals** and combinators
 - ▶ It is not possible to “consume” a signal ($\Sigma \alpha \rightarrow \beta$)
 - ▶ A value of type $\Sigma \Sigma \alpha$ is impossible in a well-typed expression
- Every temporal expression has a **current value** denoted by $e^{[c]}$

$$\frac{\Gamma \vdash e : \Sigma \alpha \quad \Gamma \vdash c : \alpha}{\Gamma \vdash e^{[c]} : \Sigma \alpha} \text{CurVal}$$

- Some current values are “freshly updated” while others are “stale”
 - ▶ Denote a fresh value by asterisk: $e^{[c]*}$
 - ▶ In Elm, current values are implemented with an `Either` type

Elm operational semantics 1: Initial values

Every temporal expression has an initial (*stale*) current value

- Every predefined **input** signal $i : \Sigma\alpha, i \in \mathcal{I}$ has an initial value: $i^{[a]}$
- **Initial** current values for all expressions are derived:

$$\frac{\Gamma \vdash (\text{constant } c) : \Sigma\alpha}{\Gamma \vdash (\text{constant } c)^{[c]} : \Sigma\alpha} \text{ConstInit}$$
$$\frac{\Gamma \vdash (\text{map2 } m \ p^{[a]} \ q^{[b]}) : \Sigma\gamma}{\Gamma \vdash (\text{map2 } m \ p \ q)^{[m \ a \ b]} : \Sigma\gamma} \text{Map2Init}$$
$$\frac{\Gamma \vdash (\text{scan } u \ e \ q) : \Sigma\beta}{\Gamma \vdash (\text{scan } u \ e \ q)^{[e]} : \Sigma\beta} \text{ScanInit}$$

Elm operational semantics 2: Updating signals

- Update steps happen only to **input signals** $s \in \mathcal{I}$ and **one at a time**
- Update steps $\mathbf{U}_{s \leftarrow a} \{ \dots \}$ are applied to the **whole program** at once:

$$\frac{\Gamma \vdash s : \Sigma \alpha \quad s \in \mathcal{I} \quad \Gamma \vdash a : \alpha \quad \Gamma \vdash e^{[c]} : \Sigma \beta \quad \Gamma \vdash c' : \beta}{\Gamma \vdash \mathbf{U}_{s \leftarrow a} \{ e^{[c]} \} \Rightarrow e^{[c]}}$$

- An update step on s will leave all other **input** signals unchanged:

$$\forall s \neq s' \in \mathcal{I} : \quad \mathbf{U}_{s \leftarrow b} \{ s^{[a]} \} \Rightarrow s^{[b]*} \quad \mathbf{U}_{s \leftarrow b} \{ s'^{[c]} \} \Rightarrow s'^{[c]}$$

- Elm has an efficient implementation:
 - ▶ The instances of input signals within expressions are not duplicated
 - ▶ Stale current values are cached and not recomputed

Elm operational semantics 3: Updating combinators

- Operational semantics does not reduce temporal expressions:
 - The whole program **remains** a static temporal expression tree
 - Only the current values are updated in subexpressions

$$\mathbf{U}_{s \leftarrow a} \left\{ (\text{constant } c)^{[c]} \right\} \Rightarrow (\text{constant } c)^{[c]} \quad \text{ConstUpd}$$

$$\begin{aligned} \mathbf{U}_{s \leftarrow a} \{ \text{map2 } m \ p \ q \} \\ \Rightarrow \left(\text{map2 } m \ \mathbf{U}_{s \leftarrow a} \{ p \}^{[v]} \ \mathbf{U}_{s \leftarrow a} \{ q \}^{[w]} \right)^{[m \ v \ w]} \end{aligned} \quad \text{Map2Upd}$$

$$\mathbf{U}_{s \leftarrow a} \left\{ (\text{scan } u \ e \ q)^{[b]} \right\} \Rightarrow \left(\text{scan } u \ e \ \mathbf{U}_{s \leftarrow a} \{ q \}^{[c]*} \right)^{[u \ c \ b]*} \quad \text{ScanPUpd}$$

- All computations during an update step are **synchronous**
 - The expression $\mathbf{U}_{s \leftarrow b} \{ e^{[c]} \}$ is reduced **after** all subexpressions of e
 - Current values are non-temporal and are evaluated **eagerly**
 - `map2` updates whenever one of its subexpressions update
 - `scan` updates only if its subexpression is freshly updated

GUI building: “Hello, world” in Elm

- The value called `main` will be visualized by the runtime

```
import Graphics.Element (..)
import Text (..)
import Signal (..)

text : Element
text = plainText "Hello, World!"

main : Signal Element
main = constant text
```

- Try Elm online at <http://elm-lang.org/try>

Example of using scan

- Specification:

- ▶ *I work only after the boss comes by and unless the phone rings*

- Implementation:

```
after_unless : (Bool, Bool) -> Bool -> Bool
```

```
after_unless (b,p) w = (w || b) && not p
```

```
boss_and_phone : Signal (Bool,Bool)
```

```
i_work : Signal Bool
```

```
i_work = scan after_unless False (boss_and_phone)
```

- Demo ([boss_phone_work.elm](#))

Typical GUI boilerplate in Elm

- A state machine with stepwise update:

`update : Command → State → State`

- A rendering function (View is either Element or Html):

`draw : State → View`

- A manager that **merges** the required input signals into one:

- ▶ may use Mouse, Keyboard, Time, HTML stuff, etc.

`merge_inputs : Signal Command`

- Main boilerplate:

`init_state : State`

`main : Signal View`

`main = map draw (scan update init_state merge_inputs)`

Some limitations of Elm-style FRP

- No higher-order signals: $\Sigma(\Sigma\alpha)$ is disallowed by the type system
- No distinction between continuous time and discrete time
- The signal processing logic is fully specified statically
- No constructors for user-defined signals
- No recursion possible in signal definition!
 - ▶ Awkward mechanisms for “tying the knot” in Elm
- No full concurrency (e.g. “dining philosophers”)

Elm-style FRP: the good parts

- Transparent, declarative modeling of data through ADTs
- Immutable and safe data structures (Array, Dict, ...)
- No runtime errors or exceptions!
- Space/time leaks are impossible!
- Language is Haskell-like but simpler for beginners
- Full type inference
- Easy deployment and interop in Web applications
- Good support for HTML/CSS, HTTP requests, JSON
- Good performance of caching HTML views
- Support for Canvas and HTML-free UI building

Part 2. Temporal logic and FRP

- Reminder (Curry-Howard): logical expressions will be types
 - ▶ ...and the axioms will be primitive terms
- We only need to control the **order** of events: no “hard real-time”
- How to understand temporal logic:
 - ▶ classical propositional logic \approx Boolean arithmetic
 - ▶ intuitionistic propositional logic \approx same but without **true** / **false** dichotomy
 - ▶ (linear-time) temporal logic LTL \approx Boolean arithmetic for *infinite sequences*
 - ▶ intuitionistic temporal logic ITL \approx same but without **true** / **false** dichotomy
- In other words:
 - ▶ an ITL type represents a **single infinite sequence** of values

Boolean arithmetic: notation

- Classical propositional (Boolean) logic: $T, F, a \vee b, a \wedge b, \neg a, a \rightarrow b$
- A notation better adapted to school-level arithmetic: $1, 0, a + b, ab, a'$
- The only “new rule” is $1 + 1 = 1$
- Define $a \rightarrow b = a' + b$
- Some identities:

$$\begin{aligned}0a &= 0, & 1a &= a, & a + 0 &= a, & a + 1 &= 1, \\a + a &= a, & aa &= a, & a + a' &= 1, & aa' &= 0, \\(a + b)' &= a'b', & (ab)' &= a' + b', & (a')' &= a \\a(b + c) &= ab + ac, & (a + b)(a + c) &= a + bc\end{aligned}$$

Boolean arithmetic: example

Of the three suspects A, B, C, only one is guilty of a crime.

Suspect A says: "B did it". Suspect B says: "C is innocent."

The guilty one is lying, the innocent ones tell the truth.

$$\phi = (ab'c' + a'bc' + a'b'c) (a'b + ab') (b'c' + bc)$$

Simplify: expand the brackets, omit aa' , bb' , cc' , replace $aa = a$ etc.:

$$\phi = ab'c' + 0 + 0 = ab'c'$$

The guilty one is A.

Propositional linear-time temporal logic (LTL)

- We work with *infinite boolean sequences* (“linear time”)

Boolean operations:

$$a = [a_0, a_1, a_2, \dots]; \quad b = [b_0, b_1, b_2, \dots];$$

$$a + b = [a_0 + b_0, a_1 + b_1, \dots]; \quad a' = [a'_0, a'_1, \dots]; \quad ab = [a_0 b_0, a_1 b_1, \dots]$$

Temporal operations:

$$\text{(Next)} \quad \mathbf{N}a = [a_1, a_2, \dots]$$

$$\text{(Sometimes)} \quad \mathbf{F}a = [a_0 + a_1 + a_2 + \dots, a_1 + a_2 + \dots, \dots]$$

$$\text{(Always)} \quad \mathbf{G}a = [a_0 a_1 a_2 a_3 \dots, a_1 a_2 a_3 \dots, a_2 a_3 \dots, \dots]$$

Other notation (from modal logic):

$$\mathbf{N}a \equiv \bigcirc a; \quad \mathbf{F}a \equiv \Diamond a; \quad \mathbf{G}a \equiv \Box a$$

- Weak Until: $p\mathbf{U}q = “p \text{ holds from now on until } q \text{ first becomes true}”$

$$p\mathbf{U}q = q + p\mathbf{N}(q + p\mathbf{N}(q + \dots))$$

LTL: temporal specification

*Whenever the boss comes by my office, I will start working.
Once I start working, I will keep working until the telephone rings.*

$$\mathbf{G}((b \rightarrow \mathbf{F}w)(w \rightarrow w\mathbf{U}r)) = \mathbf{G}((b' + \mathbf{F}w)(w' + w\mathbf{U}r))$$

*Whenever the button is pressed, the dialog will appear.
The dialog will disappear after 1 minute of user inactivity.*

$$\mathbf{G}((b \rightarrow \mathbf{F}d)(d \rightarrow \mathbf{F}t)(d \rightarrow d\mathbf{U}td'))$$

- The timer t is an external event and is *not specified* here
- Difficult to say “ x stays true until further notice”

Temporal logic redux

Designers of FRP languages must face some choices:

- LTL as type theory: do we use $\mathbf{N}\alpha$, $\mathbf{F}\alpha$, $\mathbf{G}\alpha$ as new types?
- Are they to be functors, monads, ...?
- Which temporal axioms to use as language primitives?
- What is the operational semantics? (I.e., how to compile this?)

A sophisticated example: [Krishnaswamy 2013]

- uses full LTL with higher-order temporal types and fixpoints
- uses linear types to control space/time leaks

Interpreting values typed by LTL

- What does it mean to have a value x of type, say, $\mathbf{G}(\alpha \rightarrow \alpha \mathbf{U} \beta)$??
 - ▶ $x : \mathbf{N}\alpha$ means that $x : \alpha$ will be available *only* at the *next* time tick (x is a **deferred value** of type α)
 - ▶ $x : \mathbf{F}\alpha$ means that $x : \alpha$ will be available at *some* future tick(s) (x is an **event** of type α)
 - ▶ $x : \mathbf{G}\alpha$ means that a (different) value $x : \alpha$ is available at *every* tick (x is an **infinite stream** of type α)
 - ▶ $x : \alpha \mathbf{U} \beta$ means a **finite stream** of α that may end with a β
- Some temporal **axioms** of intuitionistic LTL:

(deferred apply) $\mathbf{N}(\alpha \rightarrow \beta) \rightarrow (\mathbf{N}\alpha \rightarrow \mathbf{N}\beta)$;

(streamed apply) $\mathbf{G}(\alpha \rightarrow \beta) \rightarrow (\mathbf{G}\alpha \rightarrow \mathbf{G}\beta)$;

(generate a stream) $\mathbf{G}(\alpha \rightarrow \mathbf{N}\alpha) \rightarrow (\alpha \rightarrow \mathbf{G}\alpha)$;

(read infinite stream) $\mathbf{G}\alpha \rightarrow \alpha \mathbf{N}(\mathbf{G}\alpha)$

(read finite stream) $\alpha \mathbf{U} \beta \rightarrow \beta + \alpha \mathbf{N}(\alpha \mathbf{U} \beta)$

Elm as an FRP language

- λ -calculus with type $\mathbf{G}\alpha$, primitives `constant`, `map2`, `scan`

`map2` : $(\alpha \rightarrow \beta \rightarrow \gamma) \rightarrow \mathbf{G}\alpha \rightarrow \mathbf{G}\beta \rightarrow \mathbf{G}\gamma$

`scan` : $(\alpha \rightarrow \beta \rightarrow \beta) \rightarrow \beta \rightarrow \mathbf{G}\alpha \rightarrow \mathbf{G}\beta$

`constant` : $\alpha \rightarrow \mathbf{G}\alpha$

- (`map2` makes \mathbf{G} an applicative functor)
- Limitations:
 - ▶ Cannot have a type $\mathbf{G}(\mathbf{G}\alpha)$, also not using \mathbf{N} or \mathbf{F}
 - ▶ Cannot construct temporal values by hand
 - ▶ This language is an *incomplete* Curry-Howard image of LTL!

Conclusions

- There are some languages that implement FRP in various *ad hoc* ways
- The ideal is not (yet) reached
- Elm-style FRP is a promising step in the right direction

Abstract

In my day job, most bugs come from implementing reactive programs imperatively. FRP is a declarative approach that promises to solve these problems.

FRP can be defined as a λ -calculus that admits temporal types, i.e. types given by a propositional intuitionistic linear-time temporal logic (LTL). Although the Elm language uses only a subset of LTL, it achieves high expressivity for GUI programming. I will formally define the operational semantics of Elm. I discuss the advantages and the current limitations of Elm. I also review the connections between temporal logic, FRP, and Elm.

My talk will be understandable to anyone familiar with Curry-Howard and functional programming. The first part of the talk is a self-contained presentation of Elm that does not rely on temporal logic or Curry-Howard. The second part of the talk will explain the basic intuitions behind temporal logic and its connection with FRP.
