Tuples

Pair of values:

```
val a: (Int, String) = (123, "xyz")
```

Triple of values:

```
val b: (Boolean, Int, Int) = (true, 3, 4)
```

Tuples can be nested:

```
val c: (Boolean, (String, Int), Boolean) =
  (true, ("abc", 3), false)
```

Parts of the tuple can be accessed by number:

```
val x: (String, Int) = c._2
```

Functions on tuples:

```
def f(p: (Boolean, Int), q: Int): Boolean = p._1 \&\& (p._2 > q)
```

Pattern-matching syntax for tuples

Scala allows pattern matching in two places:

- val pattern = ... (value assignment)
- case pattern ⇒ ... (partial function)

Examples:

- val a = (1, 2, 3); val (x, y, z) = a
- val f: ((Int, Int, Int)) \Rightarrow Int = { case (x, y, z) \Rightarrow x + y + z }; f(a)

Combining tuple types with other types

We can use tuple types anywhere:

Tuple of functions:

```
val q: (Int \Rightarrow Int, Int \Rightarrow Int) = (x \Rightarrow x + 1, x \Rightarrow x - 1)
```

Sequence of tuples:

```
val s: Seq[(String, Int)] =
  Seq(("apples", 3), ("oranges", 2), ("pears", 0))
```

Tuples (esp. pairs) are used a lot in the Scala standard library...

```
zip: (Seq[A], Seq[B]) ⇒ Seq[(A, B)]
map: (Map[K, V], (K, V) ⇒ R) ⇒ Seq[R]
* Note: the syntax (a → b) means the same as the pair (a, b)
```

```
▶ toMap: Seq[(K, V)] \Rightarrow Map[K, V]
```

```
▶ toSeq: Map[K, V] \Rightarrow Seq[(K, V)]
```

Worked examples

- for a given sequence a_i , compute the sequence of pairs $b_i = (\cos a_i, \sin a_i) \text{use .map, assume a: Seq[Double]}$
- ② in a given sequence a_i , count how many times $\cos a_i > \sin a_i$ occurs use .count, assume a: Seq[Double]
- for given sequences a_i and b_i , compute the sequence of differences $c_i = a_i b_i$ (use .zip, .map, assume a, b: Seq[Double])
- **4** in a given sequence a_i , count how many times $a_i > a_{i+1}$ occurs
- for a given k > 0, compute the sequence $b_i = \max(a_{i-k}, ..., a_{i+k})$ use .sliding
- create a multiplication table as a value of type Map[(Int, Int), Int]use .flatMap
- of for a given sequence a_i , compute the combined set of the numbers a_i , $\cos a_i \sin a_i$ and find its maximum value use .map, .flatMap, .max
- from a Map[String, String] mapping names to addresses, and assuming that the addresses do not repeat, compute a Map[String, String] mapping addresses to names - use .toMap, .map
 - ► Write this as a function with type parameters Name and Address instead of the fixed type String

Exercises I

- Find all i, j within (0, 1, ..., 9) such that i + 4 * j > i * j (use .flatMap)
 - ▶ Same task for i, j, k and the condition i + 4 * j + 9 * k > i * j * k
- ② Given two sequences a: Seq[String] and b: Seq[Boolean] of equal length, compute a Seq[String] with those elements of a for which the corresponding element of b is true use .zip, .map, .filter
- Onvert a Seq[Int] into a Seq[(Int, Boolean)] where the Boolean value is true when the element is followed by a larger value; e.g. Seq(1,3,2,4) is to be converted into Seq((1,true),(3,false),(2,true))
- Given a: Seq[String] and b: Seq[Int] of equal length, and assuming that elements of b do not repeat, compute a Map[Int, String] that maps numbers from b to their corresponding strings from a
 - Write this as a function with type parameters S and I instead of the fixed types String and Int; test it with S=Boolean and I=Set[Int]
- Given a: Seq[String] and b: Seq[Int] of equal length, compute a Seq[String] that contains the strings from a ordered according to the corresponding numbers from b - use .sortBy
 - ▶ Write this as a function with type parameter S instead of String

Exercises II

- Given a Seq[(String, Int)] showing a list of purchased items (names may repeat), compute Map[String, Int] showing the total counts: e.g. given a Seq(("apple", 2), ("pear", 3), ("apple", 5)), compute Map("apple" → 7, "pear" → 3) use .groupBy, .map, .sum
 - ▶ Write this as a function with type parameter S instead of String
- ② Given a Seq[List[Int]], compute a Seq[List[Int]] where each new inner list contains the three largest elements from the initial inner list - use .sortBy, .take, .map
- Given two sets a, b of type Set[Int], compute a Set[(Int, Int)] representing the Cartesian product of the sets a and b use .flatMap
 - ▶ Write this as a function with type parameters I, J instead of Int
- * Given a Seq[Map[Person, Amount]], showing the amounts various people paid on each day, compute a Map[Person, Seq[Amount]], showing the sequence of payments for each person (assume Person and Amount are type parameters; use .flatMap, .toSeq, .groupBy)

Mathematical induction I

Computing a number from a sequence

Typical problem:

Compute an integer value from the sequence of its decimal digits

```
def fromDigits(digits: Seq[Int]): Int = ???
fromDigits(Seq(1, 3, 0, 0)) == 1300
```

Mathematical formulation uses induction

- base case: empty sequence: fromDigits(Seq()) = 0
- induction step: if fromDigits is already computed for a sequence previous..., how to compute it for a sequence with one more element: fromDigits(Seq(previous..., x)) = 10 * fromDigits(previous...) + x
 - ▶ the result still needs to be divided by 10

Translating mathematical induction into code:

- use recursion
- use standard library functions fold, scan, etc.

Mathematical induction II

Writing a recursive function by hand

- base case vs. inductive step needs to be decided in the code
- the function calls itself recursively

```
def fromDigits(digits: Seq[Int]): Int =
  if (digits.isEmpty) 0
  else {
    val x = digits.head
    val rest = digits.drop(1)
    10 * fromDigits(rest) + x
}
```

- lots of code...
 - not very different from writing a loop

Tail recursion

The "accumulator" technique

The code of fromDigits calls itself in the middle of an expression:

```
def fromDigits(...) = if (...) 0
else f(..., fromDigits(...), ...)
```

- The intermediate expression grows, causing expression overflow
 - this crashes our program with a "stack overflow" error
- To remedy this: use tail recursion,

```
@tailrec def fromDigits(...) = if (...) ... else {
  val x = ...
  fromDigits(... x ...)
}
```

- The "accumulator technique" makes some programs tail-recursive
 - add another argument that accumulates the final result

```
@tailrec def fromDigits(digits: Seq[Int], res: Int) =
  if (digits.isEmpty) res
  else fromDigits(digits.drop(1), 10 * res + digits.head)
```

Mathematical induction III

Computing a number from a sequence

The standard function foldLeft implements general induction:

- base case is the first argument to foldLeft
- induction step is represented by a function (previous, x) \Rightarrow next

```
def fromDigits(digits: Seq[Int]): Int =
  digits.foldLeft(0){ case (prev, x) \Rightarrow prev * 10 + x }
```

- see other library functions: .foldRight, .fold, .reduce
- most of these functions are tail-recursive

Mathematical induction IV

Computing a sequence from a number (iterate)

Typical problem:

- Compute the sequence of decimal digits of a given integer
 - ▶ we cannot solve this with .map, .zip, .fold etc., because the length of the resulting sequence is unknown
 - we need to "unfold" into a sequence of unknown length, and terminate it when some condition holds
- Inductive definition: given n > 0, build sequence (m_k, d_k) until (0, 0):

$$(m_0, d_0) = (n, 0)$$

 $(m_k, d_k) = \left(\frac{m_{k-1}}{10}, (m_{k-1} \mod 10)\right) \text{ for } k > 0$

The Iterator.iterate method can do this:

```
Iterator.iterate((n, 0)) { case (m, _) \Rightarrow (m / 10, m % 10) } .takeWhile{case (m, d) \Rightarrow m > 0 || d > 0 } .drop(1).map(_._2) // extract sequence of digits
```

Mathematical induction V

Computing a sequence from another sequence (scan)

Typical problem:

- Compute partial sums of the given sequence: $b_k = \sum_{i=0}^k a_i$
- Definition by induction:

$$b_0 = 0;$$

 $b_k = a_k + b_{k-1} \text{ for } k > 0$

• Example code:

```
val a = Seq(1, 2, 3, 4)
val b = a.scan(0) { (x, y) \Rightarrow x + y } // yields Seq(0, 1, 3, 6, 10)
```

Summary

What problems can we solve now?

- Compute mathematical expressions involving arbitrary recursion
- Use tail recursion when possible
- Use arbitrary inductive (i.e. recursive) formulas to:
 - convert sequences to numbers ("aggregate")
 - create new sequences from scratch
 - transform existing sequences

What problems are not solved with these tools?

Compute non-tail recursive functions without expression overflow

Worked examples

- ① Compute the smallest n such that f(f(f(...f(1)...) > 1000), where the function f is applied n times (use iterate)
 - \blacktriangleright Write this as a function taking f, 1, and 1000 as arguments
- Find the k-th largest element in an (unsorted) sequence of integers use .foldLeft
- Find the last element of a nonempty sequence use pattern matching, .drop, and tail recursion
- Implement binary search over a sorted Array[Int] use tail recursion
- **3** For a given n: Int, compute the sequence $(s_0, s_1, s_2, ...)$ defined by $s_0 = SD(n)$ and $s_k = SD(s_{k-1})$ for k > 0, where SD(p) is the sum of the decimal digits of the integer p, e.g. SD(123) = 6 (use iterate)
- For a given sequence $(s_0, s_1, s_2, ...)$ of type Iterator[T], compute the "half-speed" sequence $(s_0, s_0, s_1, s_1, s_2, s_2, ...)$ use .flatMap
- ② Cut off a given sequence $(s_0, s_1, s_2, ...)$ at a place k where an element s_k equals some earlier element s_i with i < k use .zip, .takeWhile

Exercises III

- Compute the sum of squared digits of a given integer; e.g., dsq(123)=14
 - ► Same task for an arbitrary function **f**: Int⇒Int instead of squaring
- ② For a given integer *n*, compute the sum of cubed digits, then the sum of cubed digits of the result, etc.; determine whether the resulting sequence starts repeating itself, and if so, whether it ever reaches 1
- **③** For a given integer n, compute the Collatz sequence: $c_0 = n$ and

$$c_{k+1} = \begin{cases} c_k/2 & \text{if } c_k \text{ is even,} \\ 3c_k + 1 & \text{if } c_k \text{ is odd} \end{cases}$$

- ▶ Stop the sequence when it reaches 1
- For a,b,c of type Set[Int], compute the set of all sets of the form Set(x,y,z) where x is from a, y from b, and z from c (use .flatMap)
- \$ * Same task for a Set[Set[Int]] instead of just three sets a,b,c use
 .foldLeft
