## Types and propositional logic

The Curry-Howard correspondence

The code val x: T = ... shows that we can compute a value of type T as part of our program expression

- Let's denote this proposition by  $\mathcal{CH}(T)$  "Code  $\mathcal{H}$ as a value of type  $\mathbf{T}$ "
- Correspondence between types and propositions, for a given program:

Туре	Proposition	Short notation
Т	$\mathcal{CH}(T)$	T
(A, B)	CH(A) and $CH(B)$	$A \times B$
Either[A, B]	CH(A) or $CH(B)$	$A+B$ , $A\vee B$
$A \Rightarrow B$	CH(A) implies $CH(B)$	$A \Rightarrow B$
Unit	True	1
Nothing	False	0

- Type parameter [T] in a function type means  $\forall T$
- Example: def dupl[A]: A ⇒ (A, A). The type of this function corresponds to the (valid) proposition ∀A: A ⇒ A × A

# Working with the CH correspondence I

Convert Scala types to short notation and back

#### Example 1: A disjunction type

```
sealed trait UserAction
case class SetName(first: String, last: String) extends UserAction
case class SetEmail(email: String) extends UserAction
case class SetUserId(id: Long) extends UserAction
```

• Short notation: UserAction ≡ String × String + String + Long

#### Example 2: A parameterized disjunction type

```
sealed trait Either3[A, B, C] case class Left[A, B, C](x: A) extends Either3[A, B, C] case class Middle[A, B, C](x: B) extends Either3[A, B, C] case class Right[A, B, C](x: C) extends Either3[A, B, C]
```

• Short notation: Either3<sup>A,B,C</sup>  $\equiv A+B+C$ 

## Working with the CH correspondence II

Any valid formula can be implemented in code

Proposition	Code	
$\forall A: A \Rightarrow A$	<pre>def identity[A](x:A):A = x</pre>	
$\forall A: A \Rightarrow 1$	<pre>def toUnit[A](x:A): Unit = ()</pre>	
$\forall A \forall B : A \Rightarrow A + B$	<pre>def inLeft[A,B](x:A): Either[A,B] = Left(x)</pre>	
$\forall A \forall B : A \times B \Rightarrow A$	def first[A,B](p:(A,B)):A = p1	
$\forall A \forall B : A \Rightarrow (B \Rightarrow A)$	$def const[A,B](x:A):B \Rightarrow A = (y:B) \Rightarrow x$	

- Invalid formulas cannot be implemented in code
  - Examples of invalid formulas:

$$\forall A: 1 \Rightarrow A; \ \forall A \forall B: A \lor B \Rightarrow A;$$

$$\forall A \forall B : A \Rightarrow A \times B; \quad \forall A \forall B : (A \Rightarrow B) \Rightarrow A$$

- Given a type's formula, can we implement it in code?
  - ► Example:  $\forall A \forall B : ((((A \Rightarrow B) \Rightarrow A) \Rightarrow A) \Rightarrow B) \Rightarrow B$
- Constructive propositional logic has a decision algorithm
- See code examples using the curryhoward library

# Working with the CH correspondence III

Using known properties of propositional logic and arithmetic

Are A + B,  $A \times B$  more like logic  $(A \vee B, A \wedge B)$  or like arithmetic?

• Some standard identities in logic ( $\forall A \forall B \forall C$  is assumed):

$$A \times 1 = A; \quad A \times B = B \times A$$

$$A \vee 1 = 1; \quad A \vee B = B \vee A$$

$$(A \times B) \times C = A \times (B \times C); \quad A \vee (B \times C) = (A \vee B) \times (A \vee C)$$

$$(A \vee B) \vee C = A \vee (B \vee C); \quad A \times (B \vee C) = (A \times B) \vee (A \times C)$$

$$(A \times B) \Rightarrow C = A \Rightarrow (B \Rightarrow C)$$

$$A \Rightarrow (B \times C) = (A \Rightarrow B) \times (A \Rightarrow C)$$

$$(A \vee B) \Rightarrow C = (A \Rightarrow C) \times (B \Rightarrow C)$$

- Each identity means 2 function types: X = Y is  $X \Rightarrow Y$  and  $Y \Rightarrow X$ 
  - ▶ Do these functions convert values between the types X and Y?

## Type isomorphisms I

- Types A and B are isomorphic,  $A \equiv B$ , if there is a 1-to-1 correspondence between the sets of values of these types
  - ▶ Need to find two functions  $f: A \Rightarrow B$  and  $g: B \Rightarrow A$  such that  $f \circ g = id$  and  $g \circ f = id$

Example 1: Is  $\forall A: A \times 1 \equiv A$ ? Types in Scala: (A, Unit) and A

• Two functions with types  $\forall A : A \times 1 \Rightarrow A \text{ and } \forall A : A \Rightarrow A \times 1$ :

```
def f1[A]: ((A, Unit)) \Rightarrow A = { case (a, ()) \Rightarrow a } def f2[A]: A \Rightarrow (A, Unit) = a \Rightarrow (a, ())
```

Verify that their compositions equal identity (see test code)

Example 2: Is  $\forall A : A+1 \equiv 1$ ? (The logic formula  $\forall A : A \lor 1 = 1$  is valid.)

- Types in Scala: Option[A] and Unit
  - These types are obviously not equivalent

Some logic identities yield isomorphisms of types

• Which ones do not yield isomorphisms, and why?

## Type isomorphisms II

Verifying type equivalence by implementing isomorphisms

• Need to verify that  $f_1 \circ f_2 = id$  and  $f_2 \circ f_1 = id$ 

```
Example 3: \forall A \forall B \forall C : (A \times B) \times C \equiv A \times (B \times C)
      def f1[A,B,C]: (((A, B), C)) \Rightarrow (A, (B, C)) = ???
      def f2[A,B,C]: ((A, (B, C))) \Rightarrow ((A, B), C) = ???
Example 4: \forall A \forall B \forall C : (A + B) \times C \equiv A \times C + B \times C
      def f1[A,B,C]: ((Either[A,B], C)) \Rightarrow Either[(A,C), (B,C)] = ???
      def f2[A,B,C]: Either[(A,C), (B,C)] \Rightarrow (Either[A, B], C) = ???
Example 5: \forall A \forall B \forall C : (A + B) \Rightarrow C \equiv (A \Rightarrow C) \times (B \Rightarrow C)
      def f1[A,B,C]: (Either[A, B] \Rightarrow C) \Rightarrow (A \Rightarrow C, B \Rightarrow C) = ???
      def f2[A,B,C]: ((A \Rightarrow C, B \Rightarrow C)) \Rightarrow \text{Either}[A, B] \Rightarrow C = ???
Example 6: \forall A \forall B \forall C : A + B \times C \not\equiv (A + B) \times (A + C) - "information loss"
      def f1[A,B,C]: Either[A,(B,C)] \Rightarrow (Either[A,B],Either[A,C]) = ???
      def f2[A,B,C]: ((Either[A,B],Either[A,C])) \Rightarrow Either[A,(B,C)] = ???
```

See example code for methods of testing these properties

# Type isomorphisms III

Logic CH vs. arithmetic CH for elementary ("algebraic") types

- WLOG, consider types A, B, ... that have *finite* sets of possible values
  - ▶ Sum type A + B (size |A| + |B|) provides a disjoint union of sets
  - ▶ Product type  $A \times B$  (size  $|A| \cdot |B|$ ) provides a Cartesian product of sets
  - ▶ Function type  $A \Rightarrow B$  provides the set of all maps between sets
    - ★ The size of  $A \Rightarrow B$  is  $|B|^{|A|}$
    - \* Note the identities  $a^c b^c = (ab)^c$ ,  $a^{b+c} = a^b a^c$ ,  $a^{bc} = (a^b)^c$
- If the set size (cardinality) differs, A and B cannot be equivalent
  - Logic identities give only the "equal implementability"

The meaning of the types/logic/arithmetic correspondence:

- Arithmetic formulas are related to type equivalence
- Logic formulas are related to implementability

Reasoning about types is school-level algebra with polynomials and powers

- Exp-polynomial expressions: constants, sums, products, exponentials
  - exp-poly types: primitive types, disjunctions, tuples, functions
  - polynomial types are commonly called "algebraic types"

## Using school-level algebra to reason about types

```
Recursive type: "list of integers"
```

```
sealed trait IntList final case object Empty extends IntList final case class Nonempty(head: Int, tail: IntList) extends IntList IntList \equiv 1 + Int \times IntList
```

Parameterized recursive type: "list of A", short notation: List<sup>A</sup>

```
sealed trait List[A]
final case object Nil extends List[Nothing]
final case class ::(head: A, tail: List[A]) extends List[A]
```

Short notation: (the sign "≡" means type isomorphism)

$$\begin{split} \operatorname{List}^{A} &\equiv 1 + A \times \operatorname{List}^{A} \equiv 1 + A \times (1 + A \times (1 + A \times (...)...) \\ &\equiv 1 + A + A \times A + A \times A \times A + ... + A \times ... \times A \times \operatorname{List}^{A} \end{split}$$

A curious analogy with calculus: List $(t) = 1 + t \cdot \text{List}(t)$ ; "solve" this as

List(t) = 
$$\frac{1}{1-t}$$
 = 1 + t + t<sup>2</sup> + t<sup>3</sup> + ... +  $\frac{t^n}{1-t}$ 

## Worked examples

- ① Define a parameterized type MyT[T] for the short type notation Boolean  $\Rightarrow$   $(1 + T + Int \times T + (String \Rightarrow T))$
- Transform (Either[A,B], Either[C,D]) into an equivalent sum type
- **3** Show that  $A + A \not\equiv A$  and  $A \times A \not\equiv A$ , although these hold in logic
- **4** Show that  $(A \times B) \Rightarrow C \neq (A \Rightarrow C) + (B \Rightarrow C)$  in logic
- **1** Denote Reader<sup>E,T</sup>  $\equiv E \Rightarrow T$  and implement functions with types  $A \Rightarrow \text{Reader}^{E,A}$  and Reader<sup>E,A</sup>  $\Rightarrow (A \Rightarrow B) \Rightarrow \text{Reader}^{E,B}$
- **6** Show that one cannot implement Reader[A,T] $\Rightarrow$ (A $\Rightarrow$ B) $\Rightarrow$ Reader[B,T]
- Implement  $map^{A,B}: 1+A \Rightarrow (A \Rightarrow B) \Rightarrow 1+B$  with no "information loss", that is,  $map(opt)(x \Rightarrow x) = opt$ 
  - Implement map and flatMap for Either[L,R] by preferring R over L
- **1** Denoting State  $S, T \equiv S \Rightarrow T \times S$ , implement the functions:
  - pure  $S,A:A \Rightarrow State^{S,A}$
- **②** Define recursive type NEList [A] by NEList<sup>A</sup>  $\equiv A + A \times NEList^A$ 
  - Implement map and concat for NEList (tail recursion not necessary)

#### Exercises III

- ① Define type MyTU[T,U] for  $1 + T \times U + Int \times T + String \times U$
- 2 Show that  $A \Rightarrow (B+C) \neq (A \Rightarrow B) + (A \Rightarrow C)$  in logic
- Transform (Either[A,Int], Either[A,Char], Either[A,Float]) into an equivalent type of the form  $A \times (...)$  and write the equivalence tests
- Define type OptEither<sup>A,B</sup> = 1 + A + B and implement map and flatMap for it, without information loss, preferring B over A. Get the same result using the equivalent type (1 + A) + B, i.e. Either[Option[A], B]
- Implement map for MyT[T] (see worked example 1) and for MyTU[T,U]
- Implement type-parametric functions with the following types:
  - **1** State<sup>S,A</sup>  $\Rightarrow$  (S × A  $\Rightarrow$  S × B)  $\Rightarrow$  State<sup>S,B</sup>
  - **2**  $A+Z \Rightarrow (A \Rightarrow B) \Rightarrow B+Z \text{ and } A+Z \Rightarrow B+Z \Rightarrow (A \Rightarrow B \Rightarrow C) \Rightarrow C+Z$  **3**  $flatMap^{E,A,B}$ : Reader<sup>E,A</sup>  $\Rightarrow (A \Rightarrow Reader^{E,B}) \Rightarrow Reader^{E,B}$
- $\bullet$  \* Denoting Density[Z,T] = (T $\Rightarrow$ Z) $\Rightarrow$ T, implement the functions:
  - $\bullet$  map<sup>Z,A,B</sup>: Density<sup>Z,A</sup>  $\Rightarrow$  (A  $\Rightarrow$  B)  $\Rightarrow$  Density<sup>Z,B</sup>
  - 2 flatMap $^{Z,A,B}$ : Density $^{Z,A} \Rightarrow (A \Rightarrow Density^{Z,B}) \Rightarrow Density^{Z,B}$
- 8 \* Denote Cont[R,T] =  $(T \Rightarrow R) \Rightarrow R$  and implement the functions:

  - 2 flatMap<sup>R,T,U</sup>: Cont<sup>R,T</sup>  $\Rightarrow$  ( $T \Rightarrow$  Cont<sup>R,U</sup>)  $\Rightarrow$  Cont<sup>R,U</sup>
- **1** Define recursive type  $\operatorname{Tr} 3^A \equiv 1 + A \times A \times A \times \operatorname{Tr} 3^A$ ; implement map for it.

# Working with the CH correspondence IV

Implications for designing new programming languages

- The CH correspondence maps the type system of each programming language into a certain system of logical propositions
- Scala, Haskell, OCaml, F#, Swift, Rust, etc. are mapped into the full constructive logic (all logical operations are available)
  - ► C, C++, Java, C#, etc. are mapped to *incomplete logics* without "or" and without "true" / "false"
  - ▶ Python, JavaScript, Ruby, Clojure, etc. have only one type ("any value") and are mapped to logics with only one proposition
- The CH correspondence is a principle for designing type systems:
  - Choose a complete logic, free of inconsistency
    - Mathematicians have studied all kinds of logics and determined which ones are interesting, and found the minimal sets of axioms for them
    - ★ Modal logic, temporal logic, linear logic, etc.
  - ► Provide a type constructor for each basic operation (e.g. "or", "and")

# Working with the CH correspondence V

Implications for actually writing code

#### What problems can we solve now?

- Use the short type notation for reasoning about types
- Given a fully parametric type, decide whether it can be implemented in code ("type is inhabited"); if so, *generate* the code
  - ► The Gentzen-Vorobiev-Hudelmaier algorithm and its generalizations
  - See also the curryhoward project
- Given some expression, infer the most general type it can have
  - ► The Damas-Hindley-Milner algorithm (Scala code) and generalizations
- Decide type isomorphism, simplify type formulas (the "arithmetic CH")
- Compute the necessary types before starting to write code

#### What problems cannot be solved with these tools?

- Automatically generate code satisfying properties (e.g. isomorphism)
- Express complicated conditions via types (e.g. "array is sorted")
  - ▶ Need dependent types for that (Coq, Agda, Idris, ...)
